This article provides a comprehensive overview of the fundamental concepts, methodologies, and advancements in the modelling and control of robot manipulators, emphasizing their significance and applications.

Understanding Robot Manipulators

What is a Robot Manipulator?

A robot manipulator is a mechanical arm designed to perform specific tasks by mimicking human arm movements. It comprises interconnected segments (links) joined by joints that allow movement in various degrees of freedom (DOF). Manipulators can be simple, with a few joints, or highly complex with numerous axes to perform intricate tasks.

Types of Robot Manipulators

- Serial Manipulators: Consist of links connected in a series, offering high flexibility and reach.
- Parallel Manipulators: Have multiple links connected in parallel to a common platform, providing high stiffness and precision.
- Hybrid Manipulators: Combine features of serial and parallel types for optimized performance.

Applications of Robot Manipulators

- Assembly lines in manufacturing
- Medical surgeries and prosthetics
- Space exploration and satellite servicing
- Hazardous environment handling

Modelling of Robot Manipulators

Importance of Accurate Modelling

Effective control strategies depend heavily on precise models that describe the robot's kinematics and dynamics. Accurate modelling enables simulation, analysis, and improvement of robot performance.

Kinematic Modelling

Kinematic modelling involves describing the robot's geometry and motion without considering forces or masses.

Denavit-Hartenberg (D-H) Parameters

A systematic approach to model joint and link parameters:

- Link length (a): Distance between joint axes
- Link twist (?): Angle between axes
- Link offset (d): Distance along the previous z-axis
- Joint angle (?): Rotation about the z-axis

Using D-H parameters, the forward kinematics can be derived to compute the position and orientation of the end-effector.

Dynamic Modelling

Dynamic models describe how forces and torques influence the robot's motion.

Newton-Euler Formulation

A recursive method that computes joint torques based on link velocities, accelerations, and forces.

Lagrangian Formulation

Uses the difference between kinetic and potential energy to derive equations of motion:

$\mathcal{L}$

$$L = T - V$$

\]

where (L) is the Lagrangian, (T) is kinetic energy, and (V) is potential energy.

The equations of motion derived from the Lagrangian are expressed as:

\[

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}_i}\right) - \frac{\partial L}{\partial q_i} = \tau_i$$

\]

where (q_i) are joint variables, $(\dot{q}_i)$ are their derivatives, and (τ_i) are joint torques.

Modelling and Control of Robot Manipulators: Advancing Precision and Flexibility in Automation

Introduction to Robot Manipulators

Robot manipulators are essential components in modern automation, capable of performing complex tasks with high precision and repeatability. They mimic human arm movements but with enhanced strength, speed, and endurance. The core of their effectiveness lies in accurate modeling and sophisticated control strategies. As industrial demands grow, so does the need for advanced techniques to improve manipulator performance, robustness, and adaptability.

Fundamentals of Manipulator Modelling

Understanding Kinematics

Kinematic modeling involves describing the robot's motion without considering forces or torques. It provides the relationship between joint parameters and the end-effector's position and orientation.

- Forward Kinematics: Calculates the end-effector pose from given joint variables.
- Inverse Kinematics: Determines the necessary joint variables to achieve a desired end-effector pose. This is often more complex due to multiple solutions or singularities.

Methods and Tools:

- Denavit-Hartenberg (D-H) parameters: Standardized way to assign coordinate frames to links.
- Transformation matrices: Homogeneous matrices representing position and orientation.
- Numerical algorithms: Newton-Raphson, Jacobian inverse/transpose methods for solving inverse kinematics iteratively.

Dynamic Modelling

Dynamic models describe how the manipulator responds to forces and torques, considering mass, inertia, Coriolis, centrifugal, and gravity effects.

- Lagrangian Formulation: Derives equations of motion using kinetic and potential energy, leading to the well-known Euler-Lagrange equations.
- Newton-Euler Method: A recursive approach that computes velocities and accelerations, useful for real-time control.

Dynamic Equations:

$$\mathbf{M}(\mathbf{q}) \ddot{\mathbf{q}} + \mathbf{C}(\mathbf{q}, \dot{\mathbf{q}}) \dot{\mathbf{q}} + \mathbf{G}(\mathbf{q}) = \boldsymbol{\tau}$$

Where:

- $\mathbf{q}$: Joint variables
- $\mathbf{M}(\mathbf{q})$: Inertia matrix
- $\mathbf{C}(\mathbf{q}, \dot{\mathbf{q}})$: Coriolis and centrifugal matrix
- $\mathbf{G}(\mathbf{q})$: Gravity vector
- $\boldsymbol{\tau}$: Joint torques

Accurate dynamic models are vital for advanced control schemes, simulation, and fault diagnosis.

Advanced Control Strategies for Robot Manipulators

Classical Control Approaches

- PID Control: Widely used due to simplicity but limited in handling nonlinearities and uncertainties.
